SciPy (pronounced "Sigh Pie") is a Python-based ecosystem of open-source software for mathematics, science, and engineering. In particular, these are some of the core packages:

 <p>NumPy Base N-dimensional array package</p>	 <p>SciPy library Fundamental library for scientific computing</p>	 <p>Matplotlib Comprehensive 2D Plotting</p>
 <p>IPython Enhanced Interactive Console</p>	 <p>Sympy Symbolic mathematics</p>	 <p>pandas Data structures & analysis</p>

“I would like to write a L^AT_EX script that produces all the prime numbers between the numbers n and m , where $n < m$. How can I do this? I feel it should not be that hard, but I cannot seem to program it.”

— Kevin[†]

[†]tex.stackexchange.com/questions/134305/how-to-produce-a-list-of-prime-numbers-in-latex/134366#134366

The first 30 prime numbers are 2, 3, 5, 7, 11, 13, 17, 19, 23, 29, 31, 37, 41, 43, 47, 53, 59, 61, 67, 71, 73, 79, 83, 89, 97, 101, 103, 107, 109, and 113. You may not find this fact very startling; but you may be surprised to learn that the previous sentence was typeset by saying

`The first thirty prime numbers are \primes{30}.`

T_EX did all the calculation by expanding the `primes` macro, so the author is pretty sure that the list of prime numbers given above is quite free of typographic errors.

Evaluating Expressions With `\py`

A Gentle
Introduction to
Python \TeX

Overview

A Question of Primes

**Introduction to
Python \TeX**

Mathematics with
SymPy

Plots with matplotlib

Web Services

Conclusions

Extra Examples

The macro `\py{expression}` evaluates a Python expression and typesets its **value**.

Did you know that $2^{65} = \code{\py{2**65}}$?

Did you know that $2^{65} = 36893488147419103232$?

Evaluating Expressions With `\pyc`

A Gentle
Introduction to
PythonTeX

Overview

A Question of Primes

Introduction to
PythonTeX

Mathematics with
SymPy

Plots with matplotlib

Web Services

Conclusions

Extra Examples

The macro `\pyc{expression}` evaluates a Python expression and typesets anything that it **prints**.

Did you know that $2^{65} = \text{\pyc{print(2**65)}}?$

Did you know that $2^{65} = 36893488147419103232?$

While “printing” adds little in this case, it is important for more complex examples.

Sessions

A Gentle
Introduction to
PythonTeX

Overview

A Question of Primes

**Introduction to
PythonTeX**

Mathematics with
SymPy

Plots with matplotlib

Web Services

Conclusions

Extra Examples

`py`, `pyc`, and `pycode` all have an optional `session` argument.

This argument determines the name of the Python session in which the code is executed.

Sessions with different names may be executed in parallel providing a speedup.

If a session is not specified, then the default session is used.

Introducing `pythontexcustocode`

A Gentle
Introduction to
PythonTeX

Overview

A Question of Primes

Introduction to
PythonTeX

Mathematics with
SymPy

Plots with matplotlib

Web Services

Conclusions

Extra Examples

```
\begin{pythontexcustocode}{py}
def makeTable(lo, hi):
    print(r"\begin{tabular}{c|c}")
    print(r"$m$ & $2^m$ \\ \hline")
    for m in range(lo, hi + 1):
        print(r"%d & %d \\ " % (m, 2**m))
    print(r"\end{tabular}")
\end{pythontexcustocode}
```

The `pythontexcustocode` environment evaluates the code block at the start of each “session” – which makes it a great place to define well-tested functions.

```
\begin{pythontexcustocode}{py}
python code block
\end{pythontexcustocode}
```

Generating Tables From a Library Function

With the import statement the module name is needed each time a member of the module is used.

To avoid this, a `from import` statement can be used.

This can shadow other functions and should be used with care.

```
\begin{pythontexcustcode}{py}
from math import factorial
\end{pythontexcustcode}
```

```
\pym{makeTableFromFunction(30, 33, factorial, "$m!$")}
```

m	$m!$
30	265252859812191058636308480000000
31	8222838654177922817725562880000000
32	26313083693369353016721801216000000

Plots with matplotlib

Web Services

Conclusions

Extra Examples

Many powerful and freely available web services can be accessed though the libraries of Python.

Python has excellent JSON, XML and networking libraries.

The first web service we will use is Google's Geocoding API.

Geocoding is the process of converting an address into geographic coordinates such as latitude and longitude.

Reverse geocoding is the process of converting geographic coordinates into a human-readable address.

Using Google's Geocoding Service

Extra Examples

```
def showGoogleMap(address, zoomlevel):  
    # Find the latitude and longitude of the address  
  
    # Build a web page with the JavaScript needed to load  
    # a Google Map at the given location and zoom level  
  
    # Save the web page to a temporary file  
  
    # Use showWebpage to display the map
```

Conclusions

Extra Examples

- ▶ PythonTeX adds significant processing time
Appropriate use of sessions can reduce this time, but there is still a large overhead.
- ▶ Debugging Python code within TeX is difficult
Test complex Python code outside of TeX first
- ▶ TeX macros that have arguments generated by Python fail on first processing step
Add such TeX macros from within Python
- ▶ Use parentheses for print statements: `print(x)`.
- ▶ Be clear of the differences between `\py` and `\pyc`.
- ▶ When using Beamer use the frame option `fragile=singleslide` if able.
- ▶ Be skeptical of SymPy results.
- ▶ If all else fails delete the `pythontex-files` folder.

```
from urllib2 import Request
def shortenURL(longURL):
    # Build the data needed to call the Goggle API
    url = "https://www.googleapis.com/urlshortener/v1/url"
    query = {"longUrl": longURL, "key": googleAPIKey}
    data = json.dumps(query)
    request = Request(url, data,
        {"Content-Type": "application/json"})

    # Fetch and parse
    result = json.load(urlopen(request))
    shortURL = result["id"]
    print(r"\url{%s}%" % shortURL)
```

Here is a short url `\pyc{shortenURL(`
`"http://mirror.jmu.edu/pub/CTAN/macros/latex/contrib/pythontex/pythontex.pdf")}`

Here is a short url <http://goo.gl/sfT8S5>.
